

Chemistry 344: Spectroscopy and Spectrometry Problem Set 3

Name (print): _____

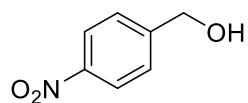

TA Name (print): _____

- I. The NMR spectra of *p*-nitrobenzyl alcohol are provided below.

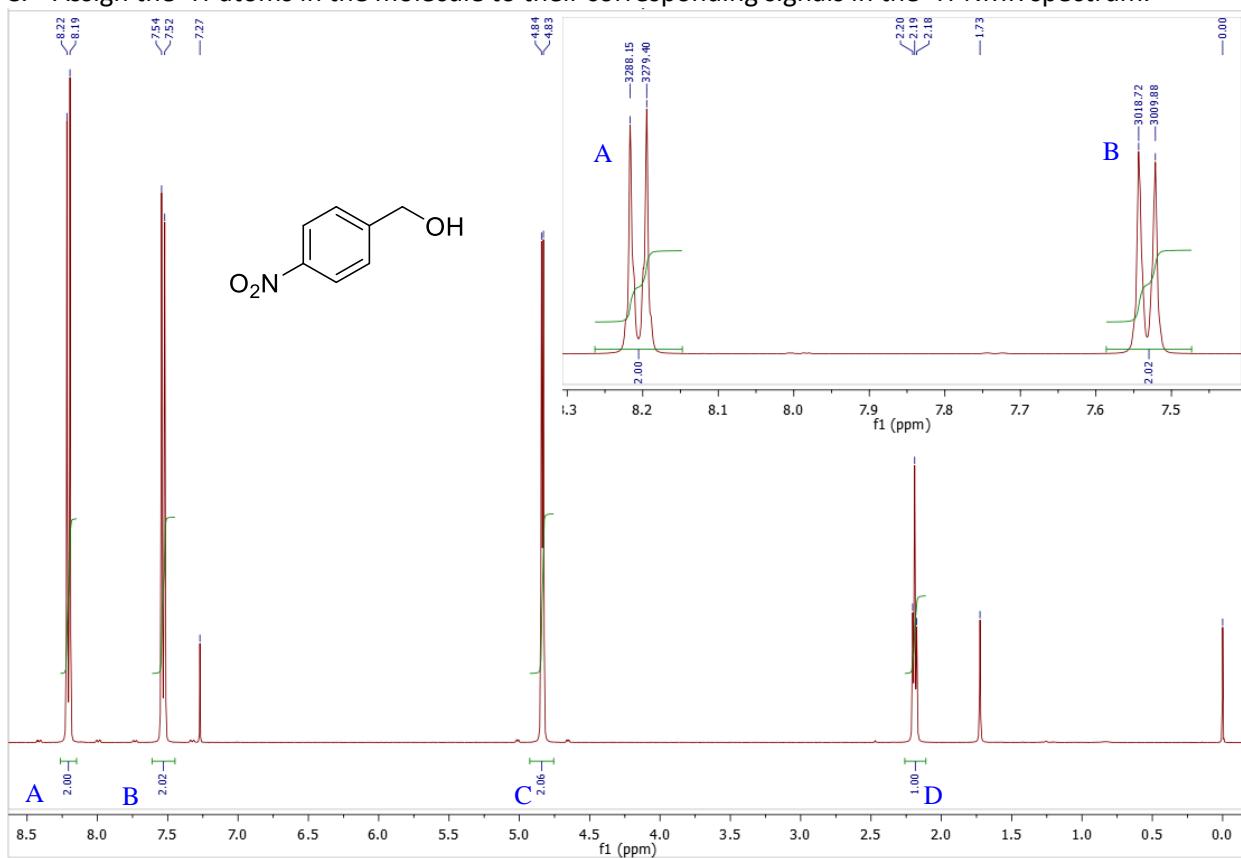

- A. In the ^{13}C -NMR APT spectrum, assign the hybridization of the ^{13}C -atoms in *p*-nitrobenzyl alcohol responsible for each signal. Identify any key functional group signals and label each ^{13}C -atom signal with the number of H-atoms attached.

- B. Predict the ^1H -NMR chemical shift for each ^1H -atom in the molecule using empirical (Curphy-Morrison) parameters.

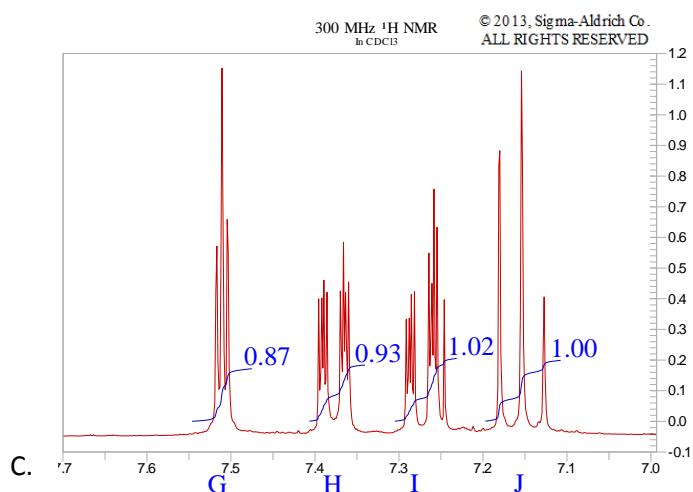

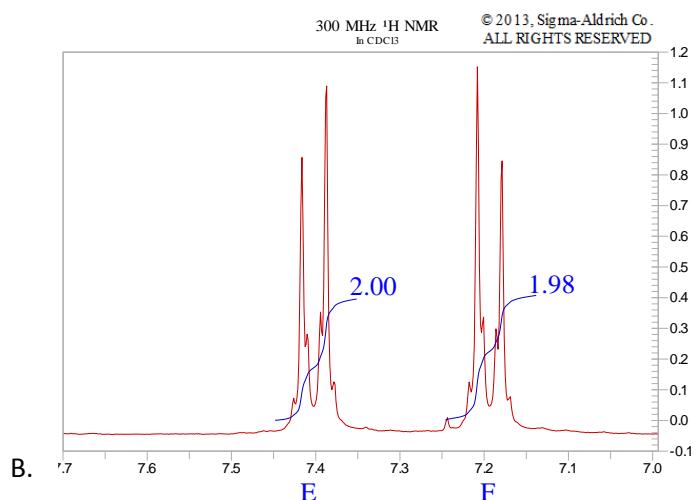

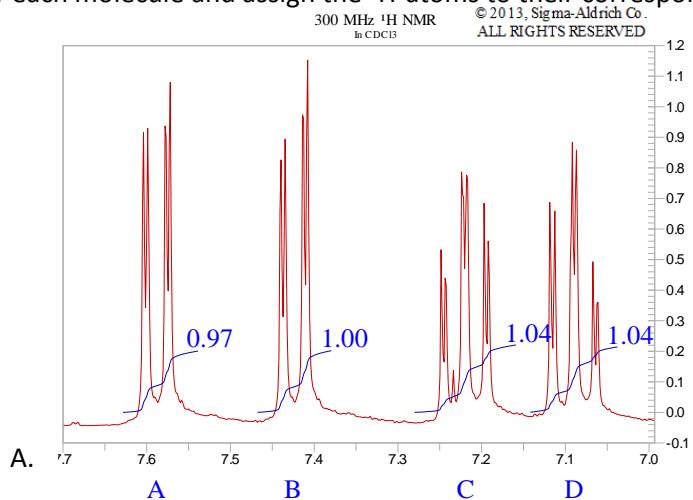

C. Assign the ^1H -atoms in the molecule to their corresponding signals in the $^1\text{H-NMR}$ spectrum.

D. How well do the Curphy-Morrison parameters predict the observed $^1\text{H-NMR}$ chemical shifts?

E. Rationalize the intense deshielding and resultant downfield shift of the ^1H -atoms attached *ortho* to the nitro group by providing a series of resonance structures. *For all resonance structures in Chem 344, you must properly show all lone pairs and formal charges.*

- II. The three ^1H -NMR spectra below from 7.0 – 7.7 ppm correspond to three bromochlorobenzenes; identify each molecule and assign the ^1H -atoms to their corresponding signals.

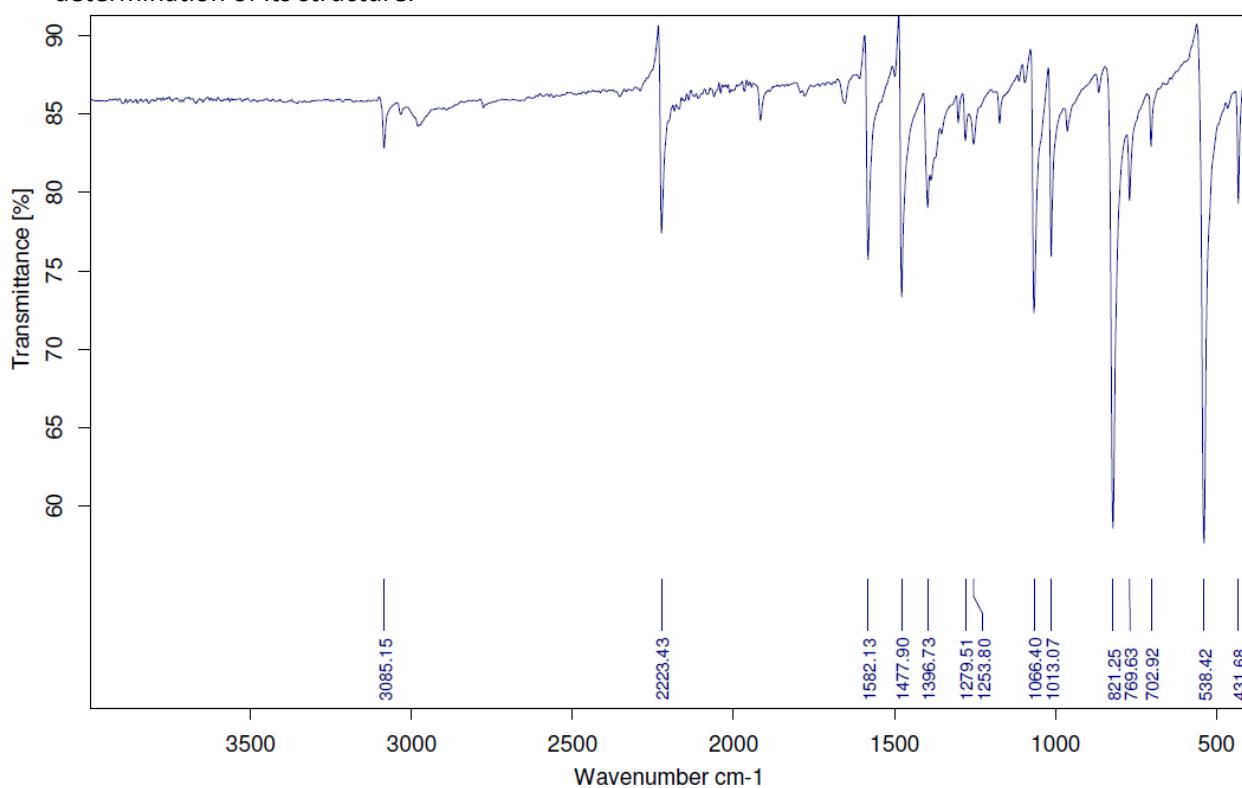

III. For the IR, ¹H-NMR and ¹³C-NMR spectra shown below for C₇H₄BrN, analyze the structure and each of the spectra as instructed.

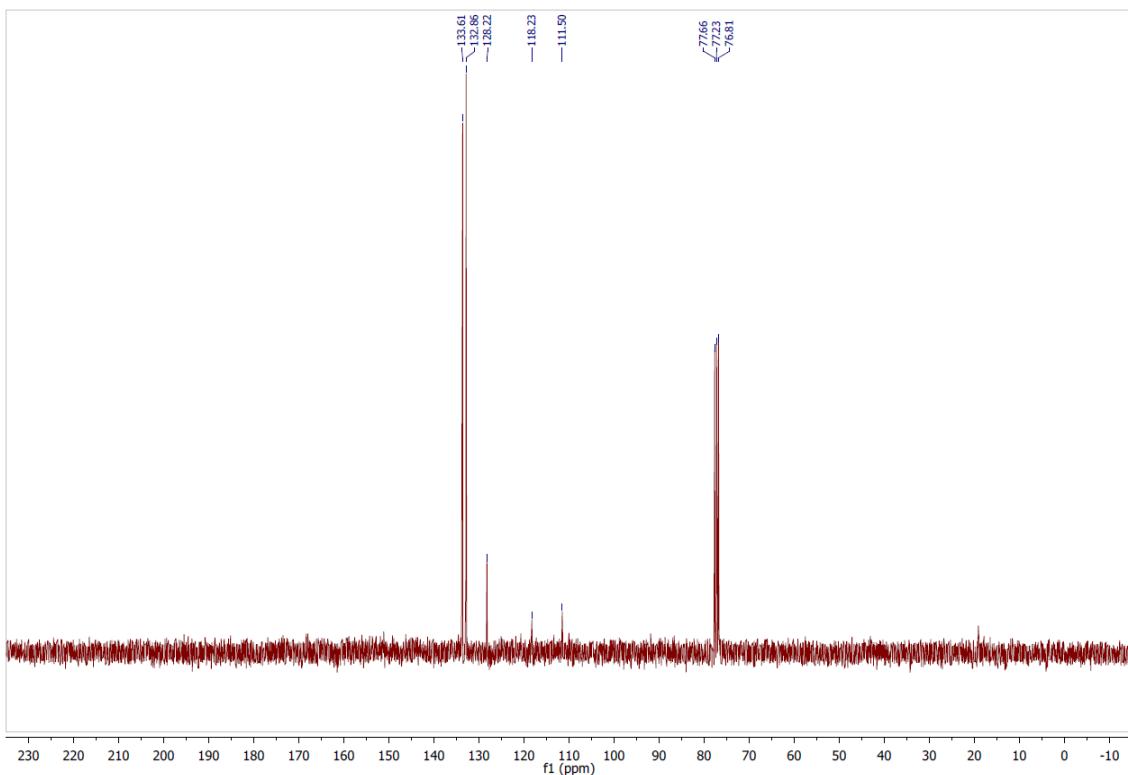

- A. What is the unsaturation number (**U**) or index of hydrogen deficiency (**IHD**)? What does this indicate about which functional groups are possible for this molecule?

$$U = IHD = \frac{2C + 2 + N - H - X}{2}$$

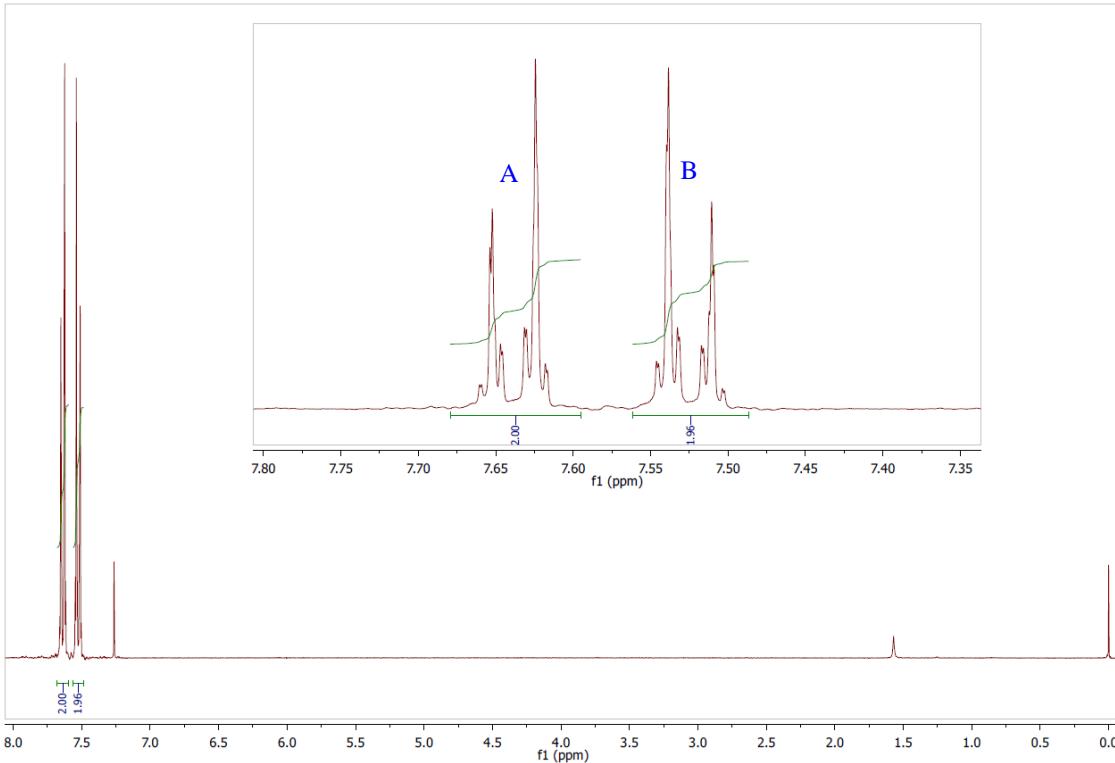

- B. The IR spectrum of C₇H₄BrN is provided below; identify any key absorptions that will assist in the determination of its structure.

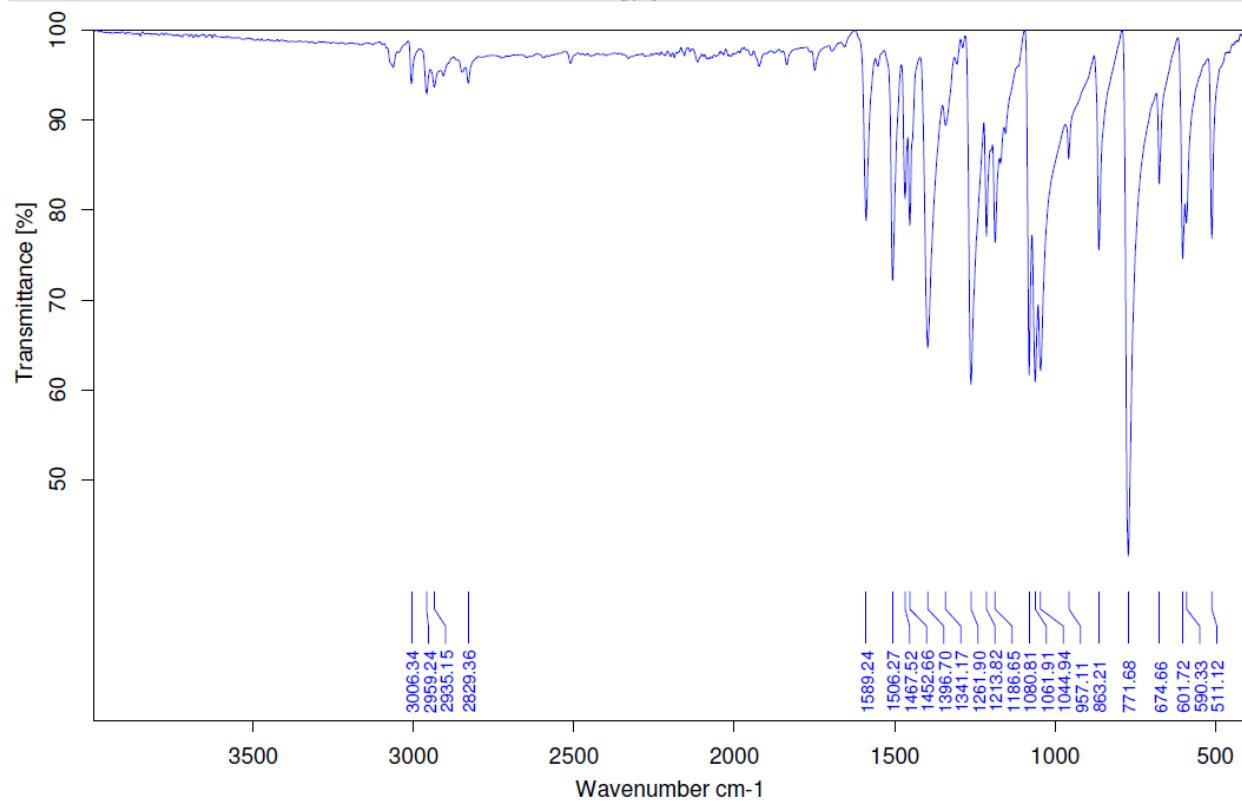

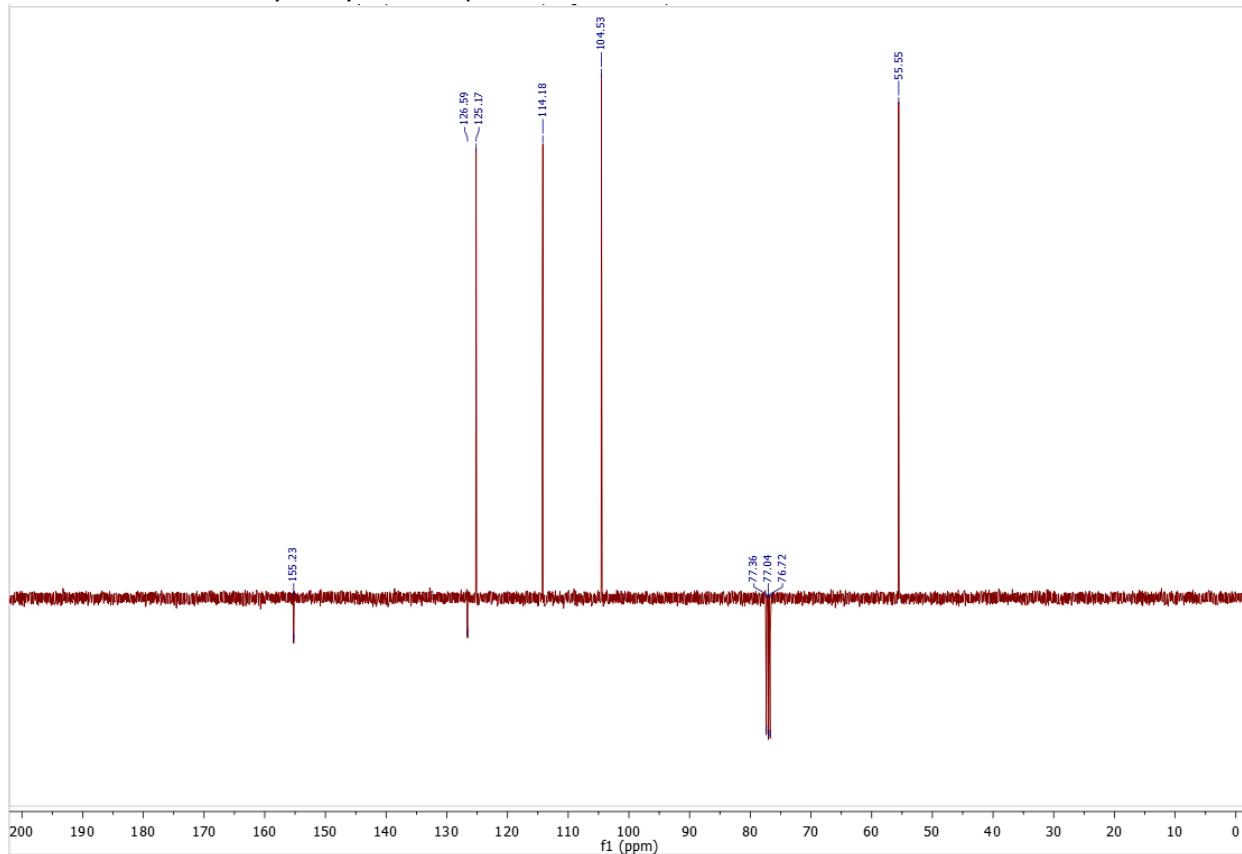

- C. The ^{13}C -NMR spectrum of $\text{C}_7\text{H}_4\text{BrN}$ is provided below; identify the hybridization and likely functional group identity of each ^{13}C -atom signal. Explain why the signals at 133.61 and 132.86 ppm are so intense and what that indicates about the structure.

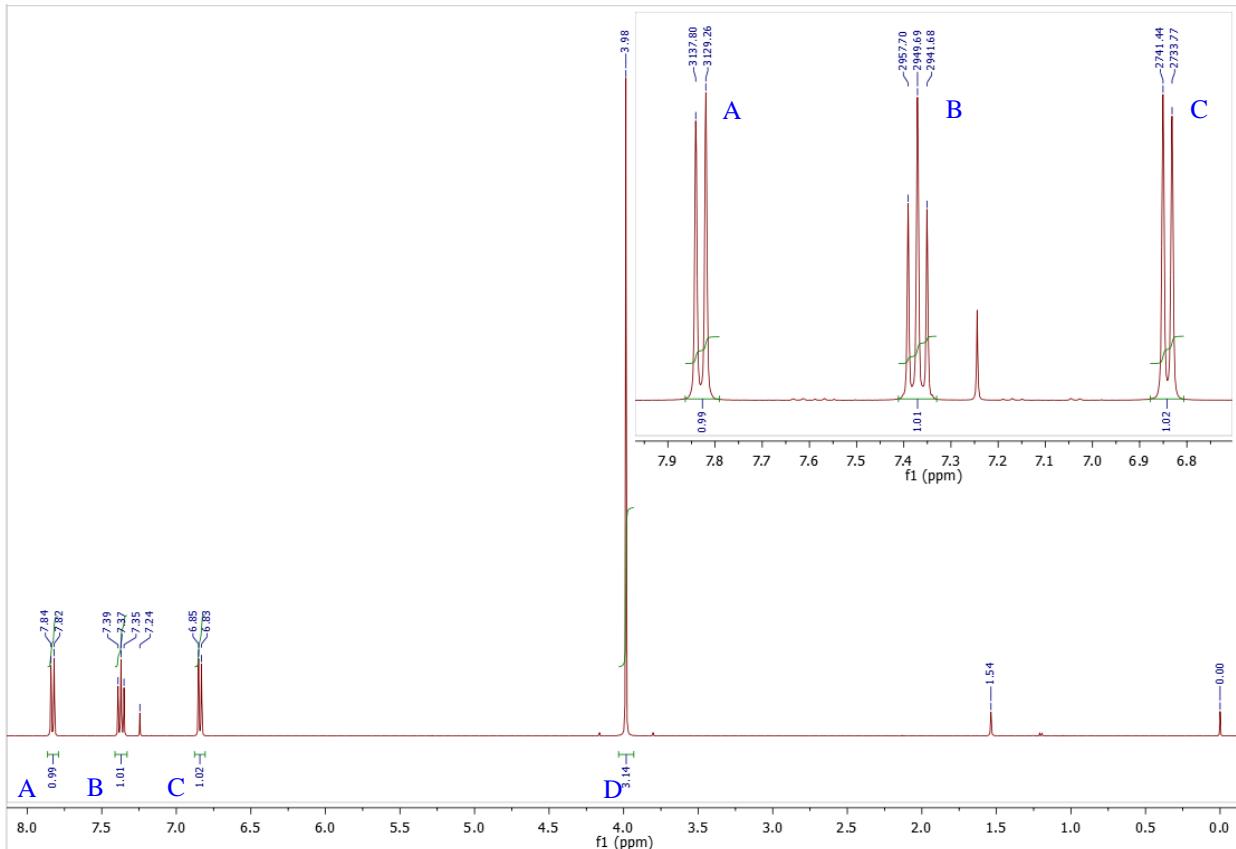

- D. The ^1H -NMR spectrum of $\text{C}_7\text{H}_4\text{BrN}$ is provided below; determine the structure. Assign each of the ^1H -atoms in the molecule to a signal on the spectrum using the key provided.

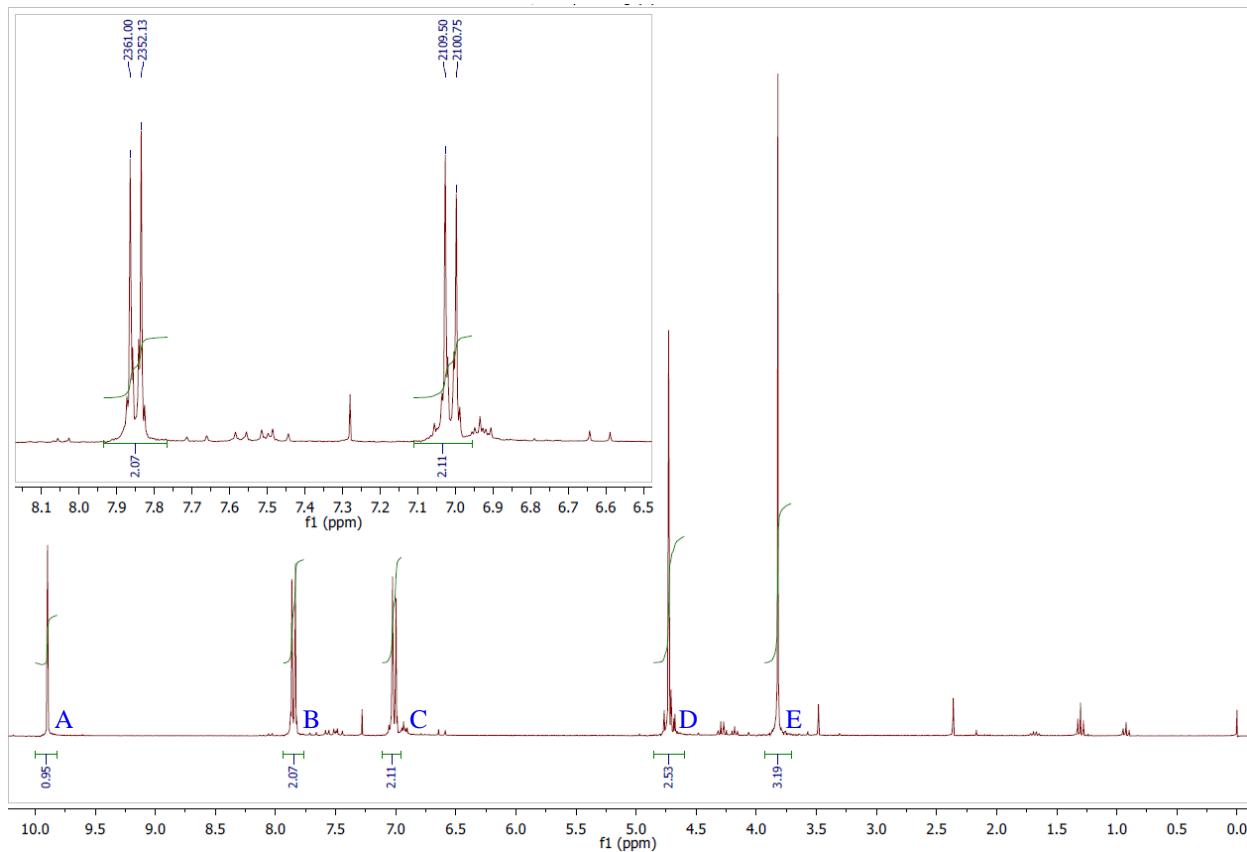

IV. Determine the structure of the molecule with formula C₁₂H₁₂O₂ that corresponds to the spectra shown below. *Fully analyze each spectrum.*

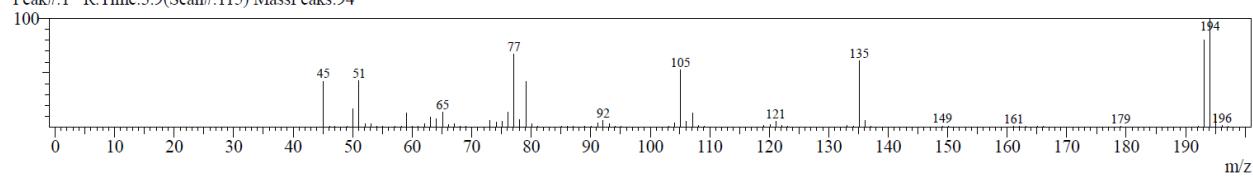

- V. The subsequent IR, EI-Mass, ^1H -NMR and ^{13}C -NMR spectra were obtained from the product of an $\text{S}_{\text{N}}2$ reaction of 4-hydroxybenzaldehyde and methyl bromoacetate. Predict the product, determine its structure and fully analyze the spectra.
-
- A. Predict the structure of the product and the ^1H -NMR chemical shifts of its ^1H -atoms using either empirical parameters or a series of resonance structures.

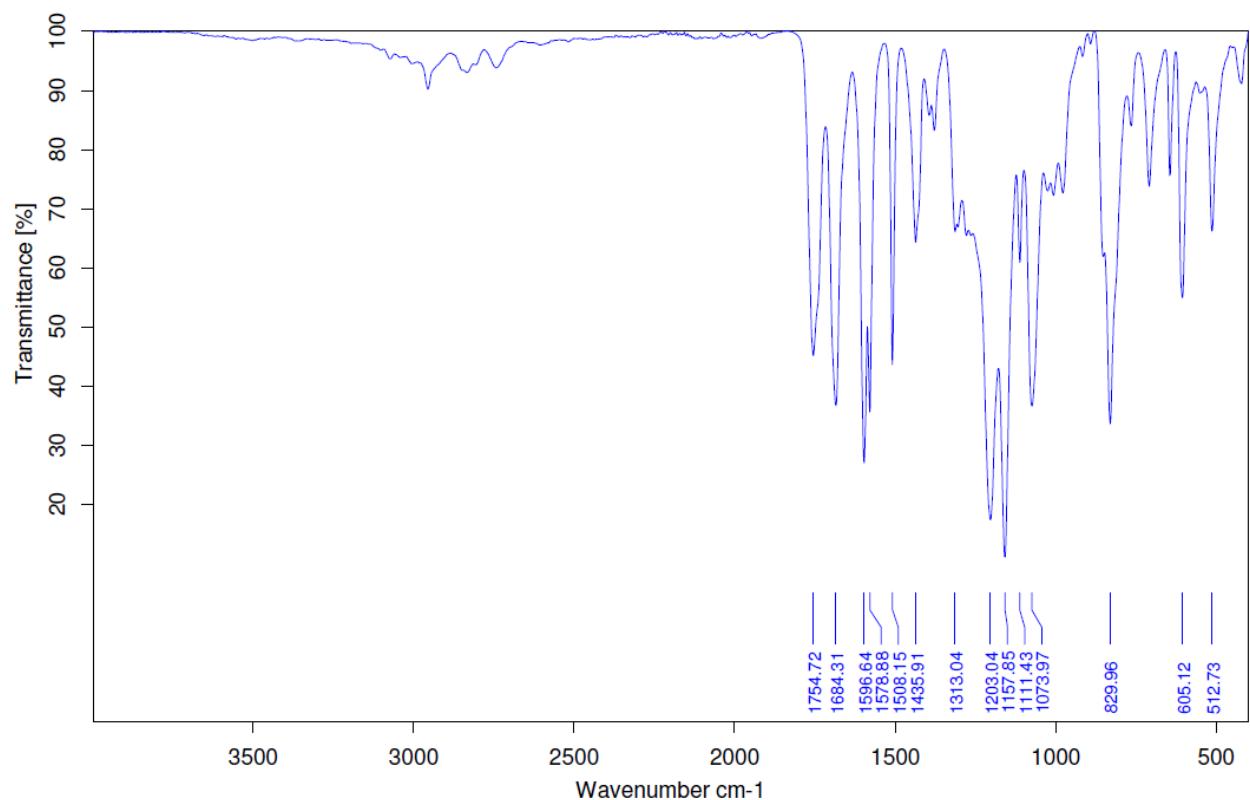

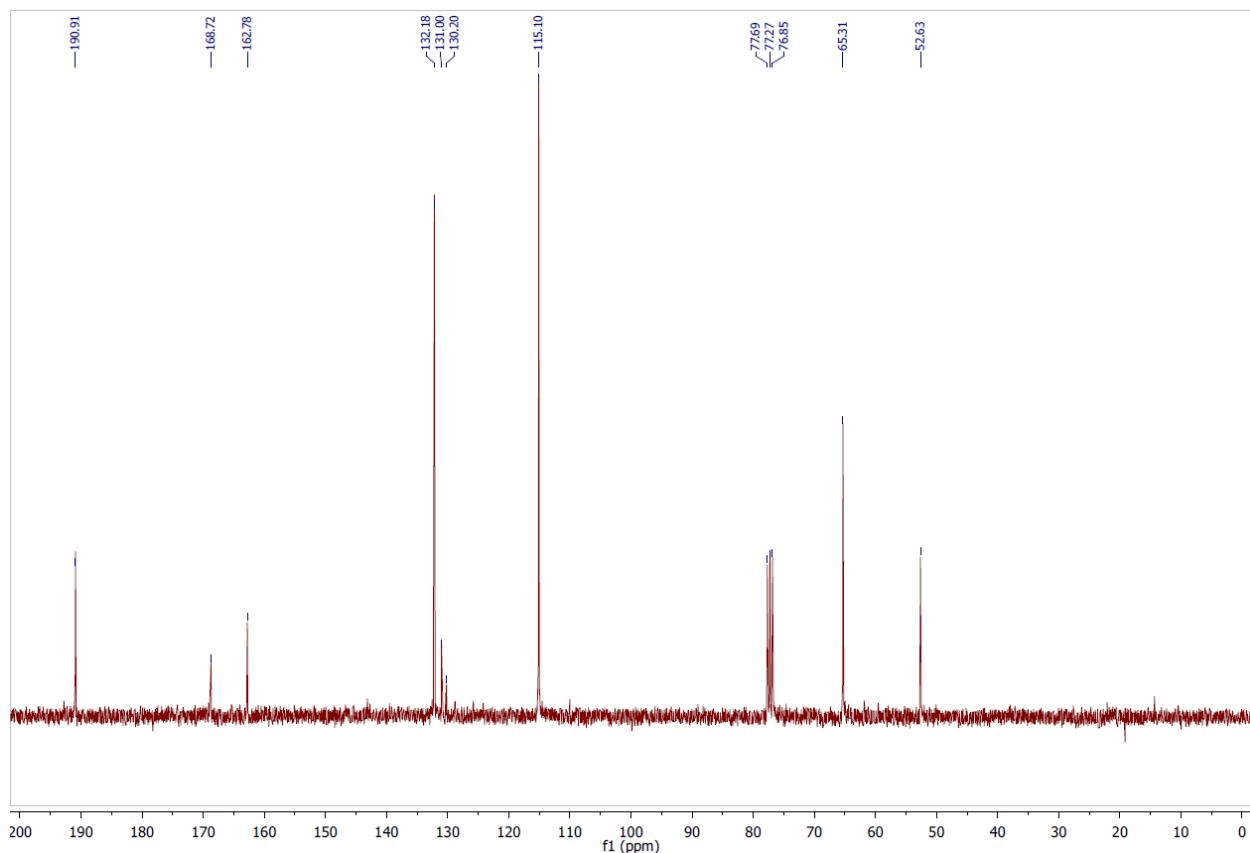

B. The ¹H-NMR spectrum contains a number of impurities. What evidence is present of an ethyl ester or propyl ester impurity?

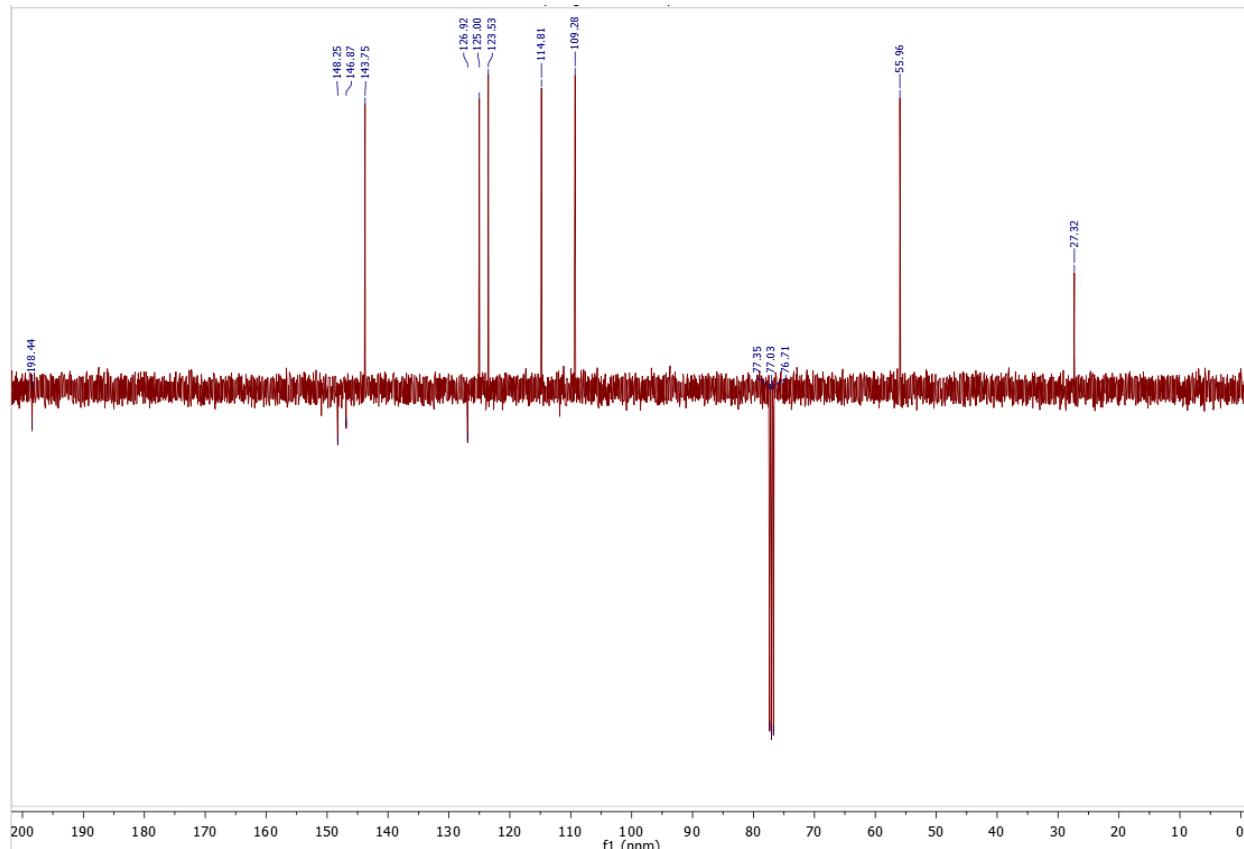

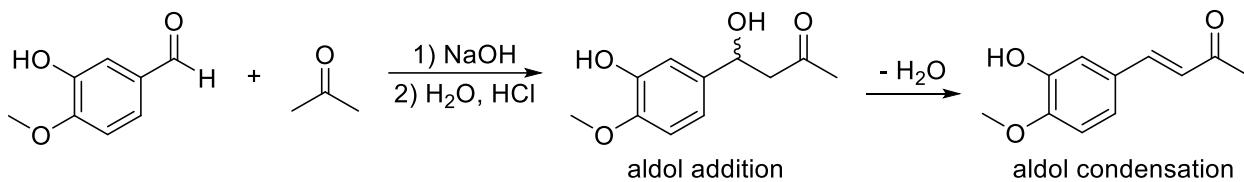

Peak#:1 R.Time:3.9(Scan#:115) MassPeaks:94

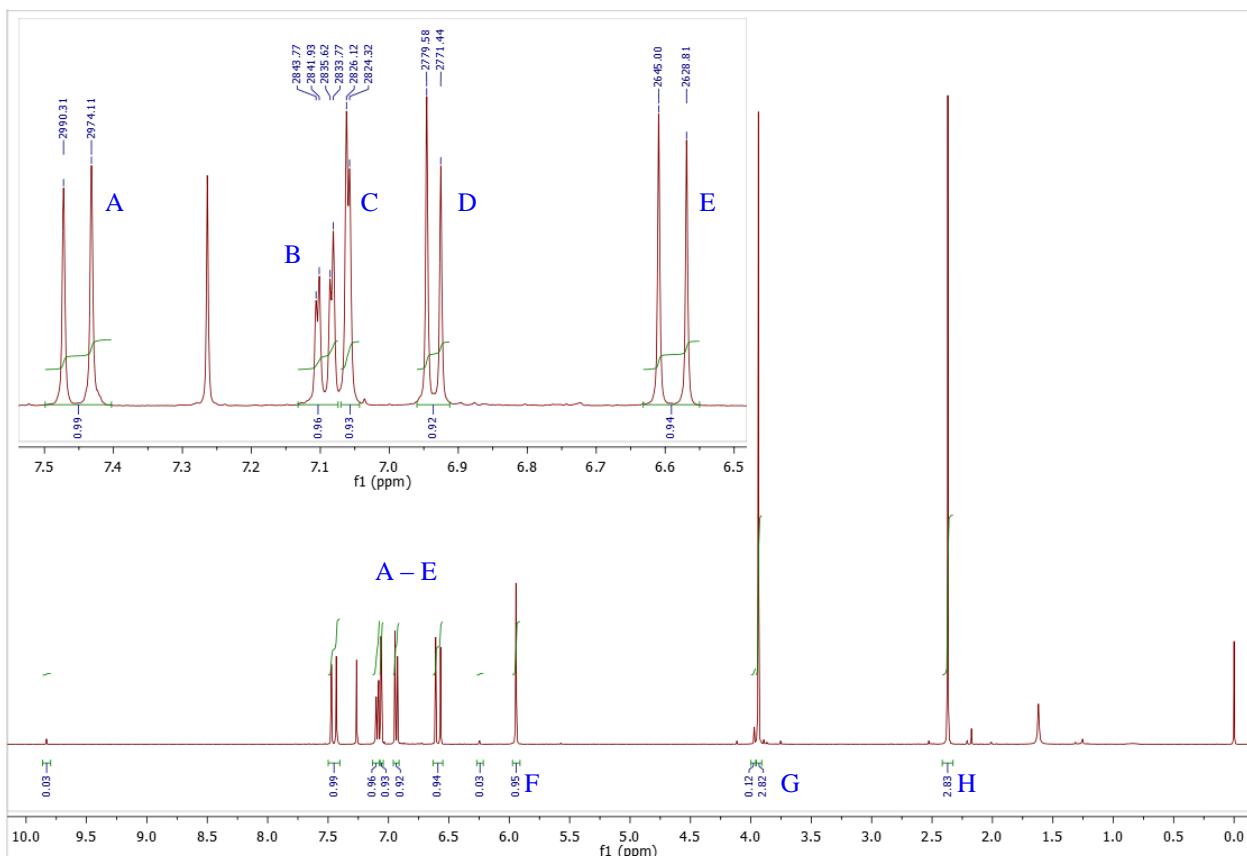

Chem 344 – University of Wisconsin

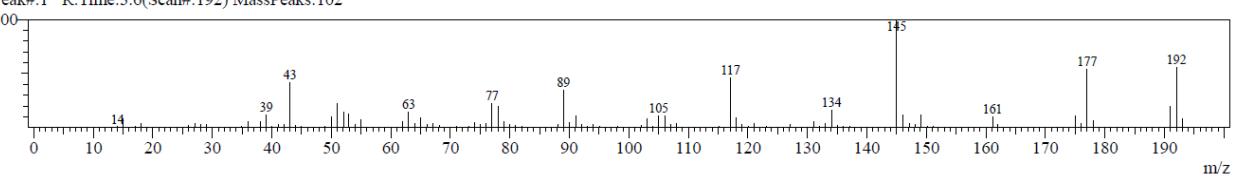

VI. Vanillin and acetone were reacted in basic aqueous conditions. Reactions such as these can lead to aldol addition or condensation products depending on the aldehyde and ketone chosen, the concentration of the base used, and the temperature of the reaction. Use the subsequent spectra to determine the outcome of the reaction.

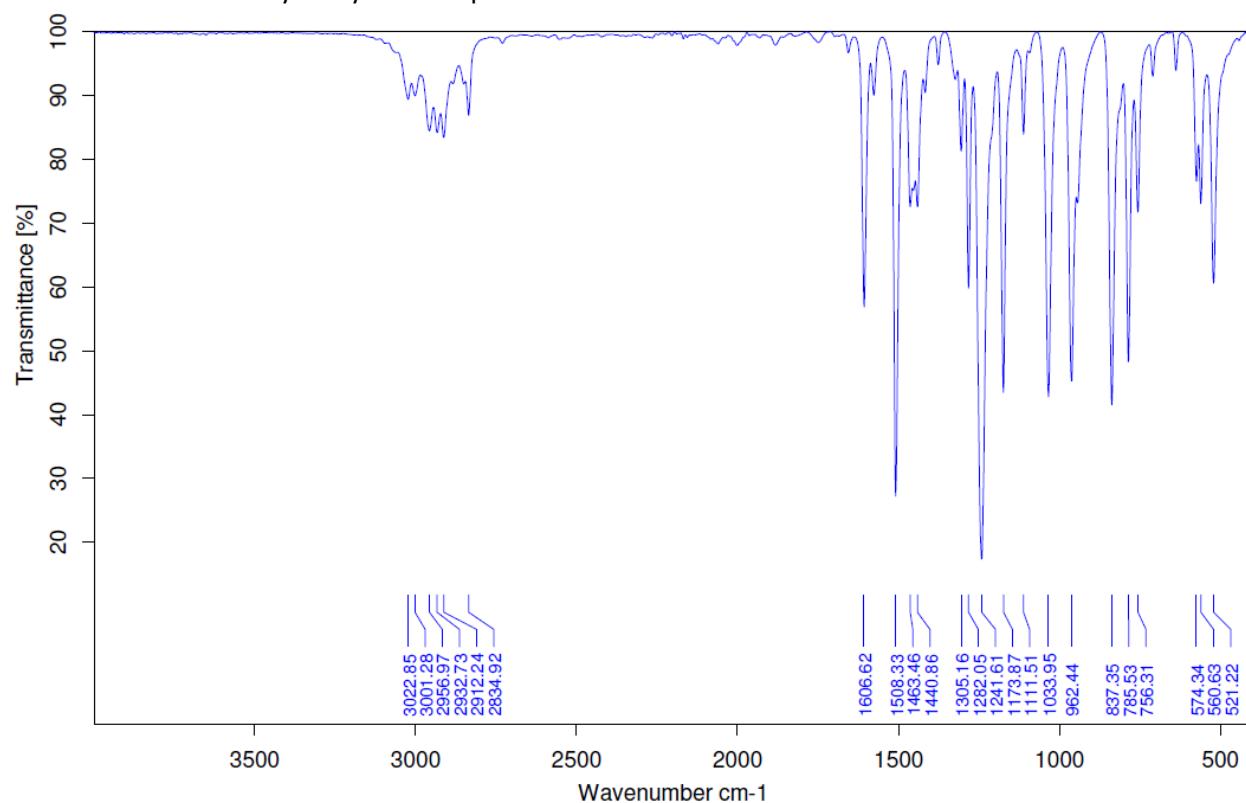

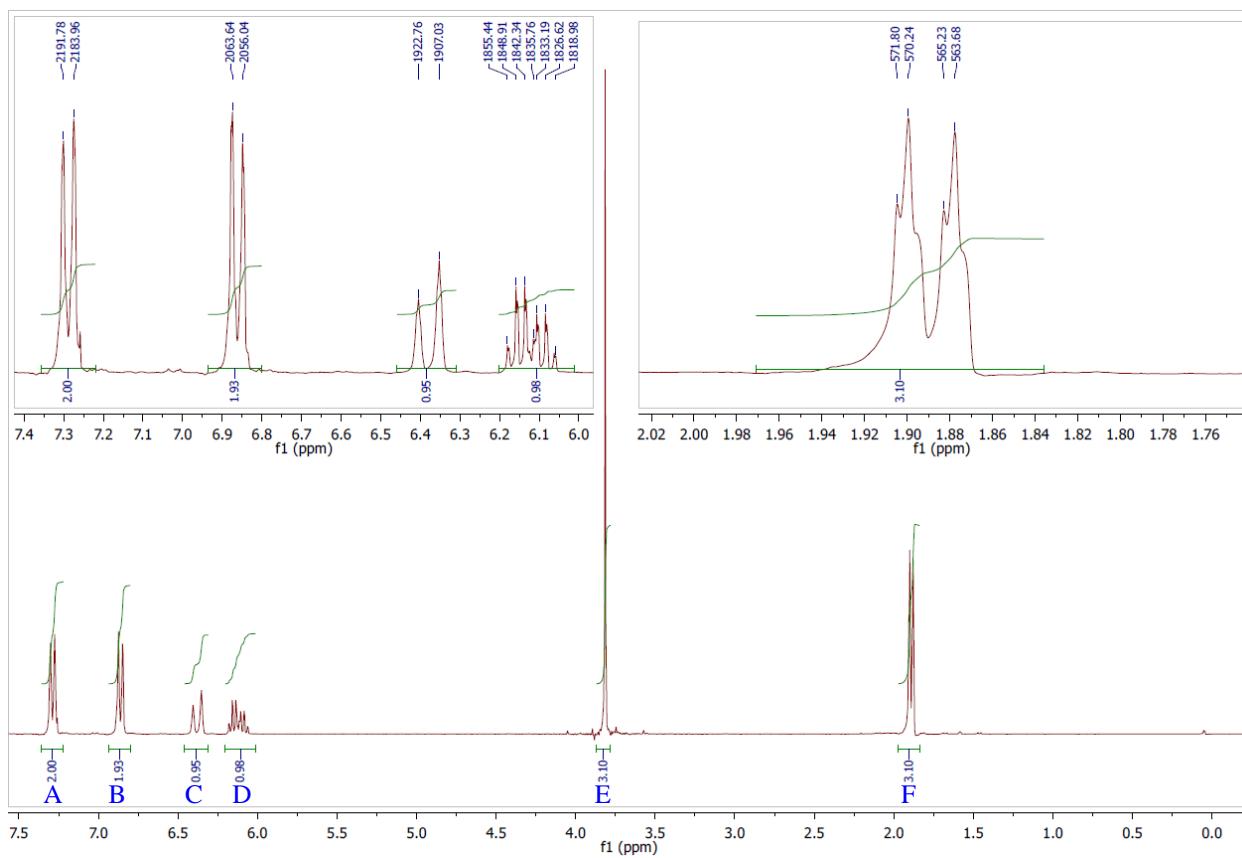

Peak#:1 R.Time:3.6(Scan#:192) MassPeaks:102

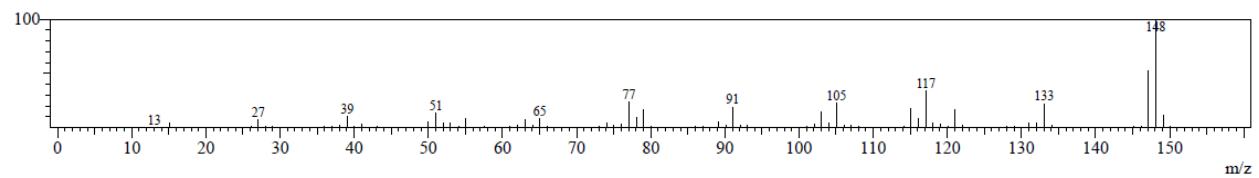

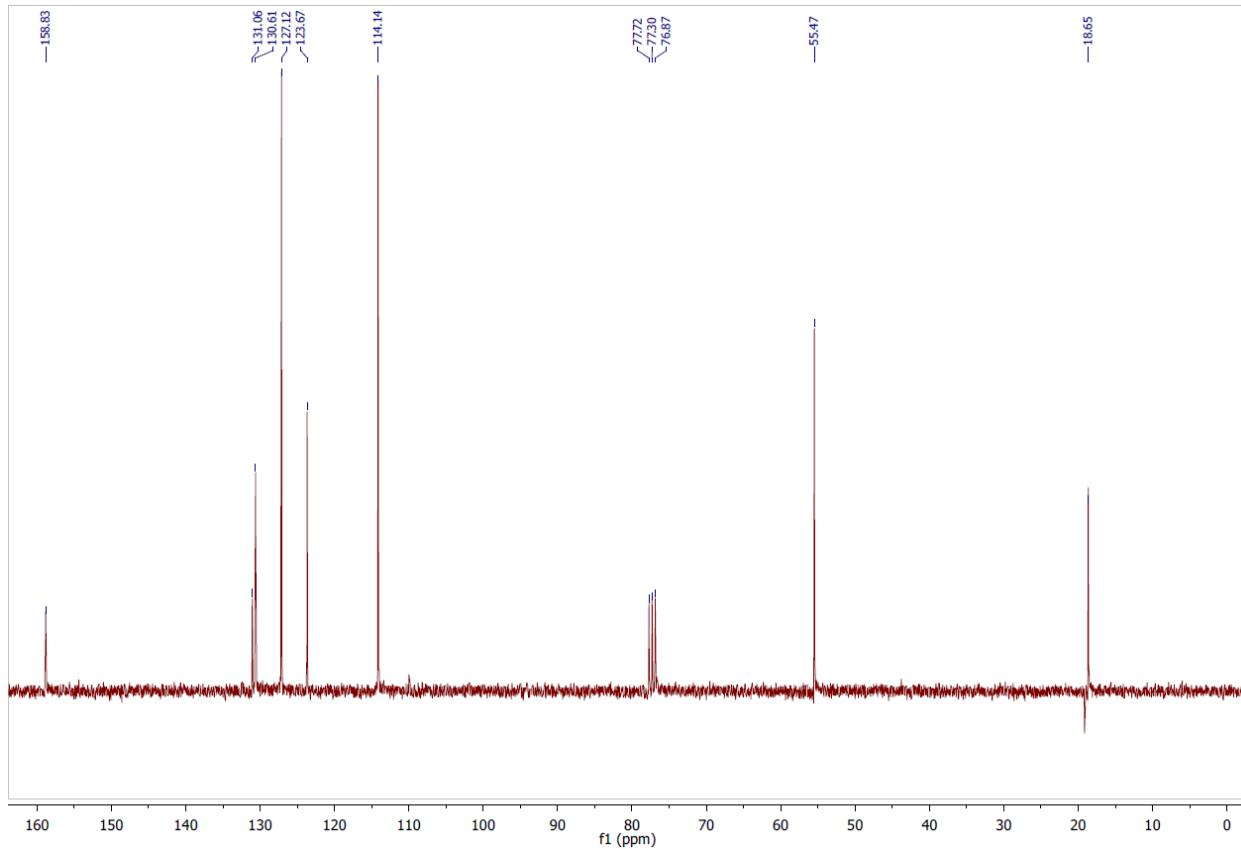

- VII. Determine the structure of the molecule with formula $C_{10}H_{12}O$ that corresponds to the spectra shown below. Fully analyze each spectrum.

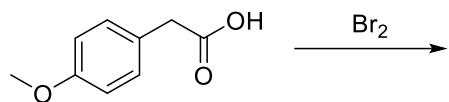

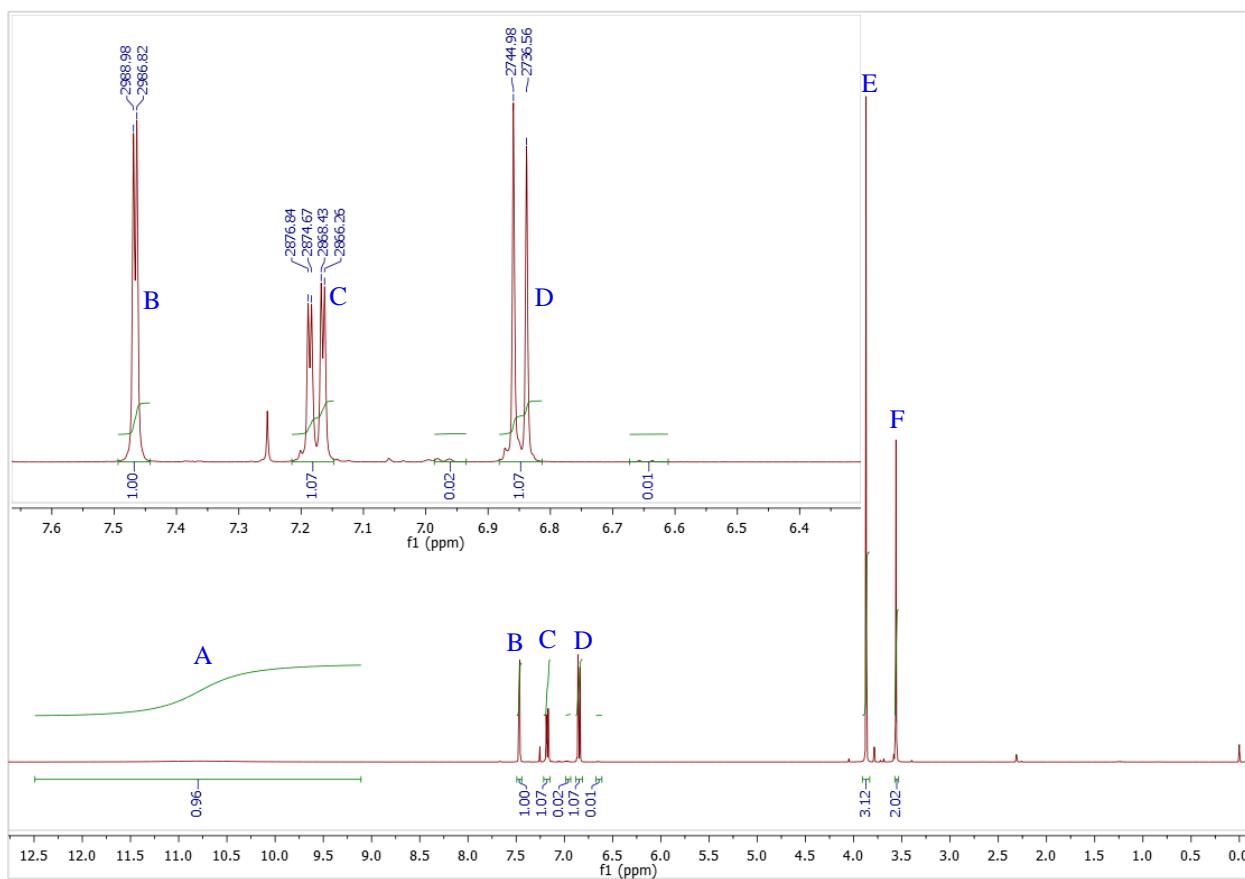

Chem 344 – University of Wisconsin

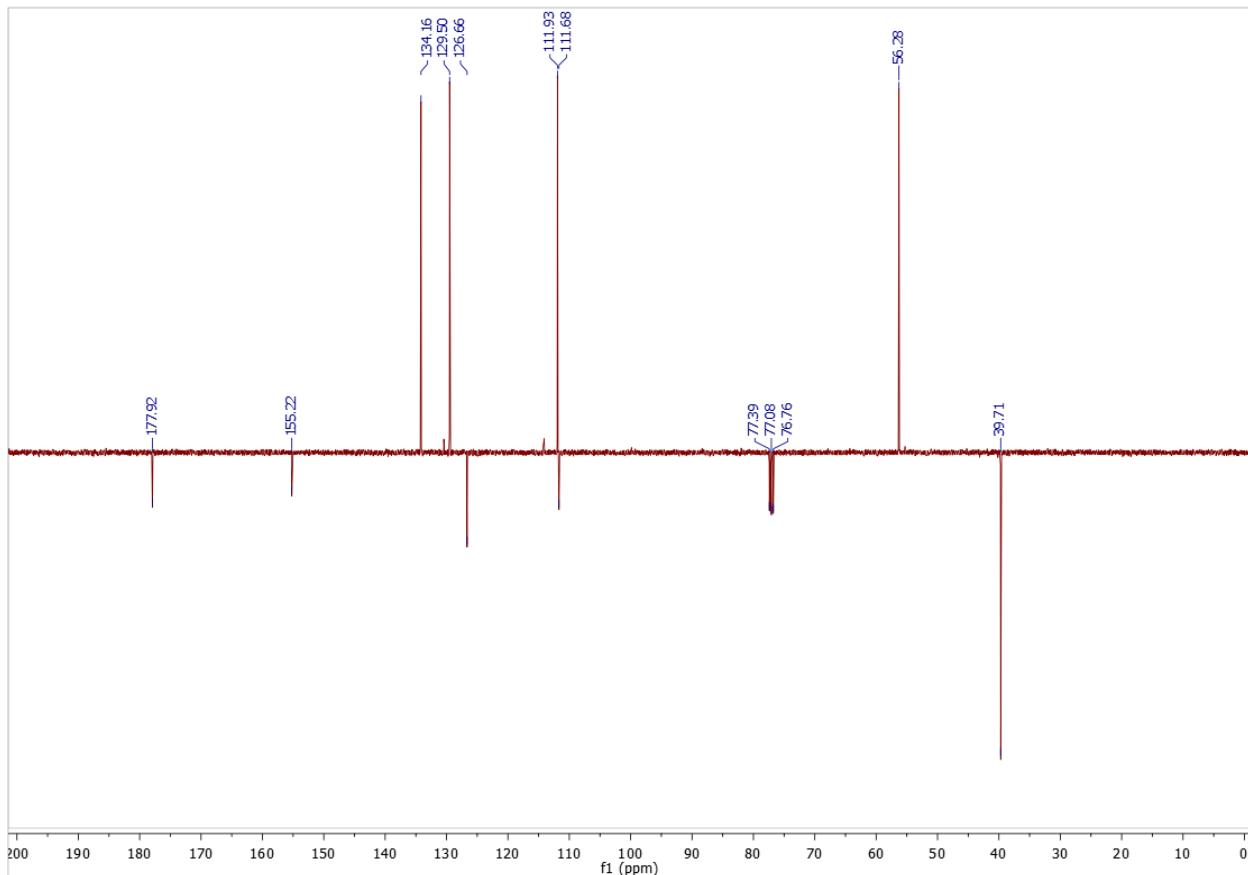

VIII. In an electrophilic aromatic substitution, 4-methoxyphenylacetic acid reacts with bromine without the need for a catalyst. Use the $^1\text{H-NMR}$ and $^{13}\text{C-NMR}$ spectra that follow to determine the identity of the major product of the reaction. Assign the $^1\text{H-NMR}$ and $^{13}\text{C-NMR}$ spectra.

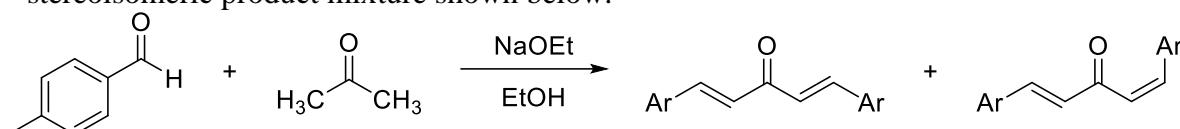

- A. Several $^1\text{H-NMR}$ signals of the starting material are discernable in the $^1\text{H-NMR}$ and $^{13}\text{C-NMR}$ spectra. Identify and assign these signals. Using the $^1\text{H-NMR}$ spectrum calculate the approximate ratio of product to starting material.

- B. Rationalize the ¹H-NMR chemical shifts of each ¹H-atom attached to the aromatic ring of the product (relative to the ¹H-atoms in benzene) using a series of resonance structures. Clearly state how the charge distribution depicted in the resonance structures rationalizes the chemical shift of the ¹H-atoms.

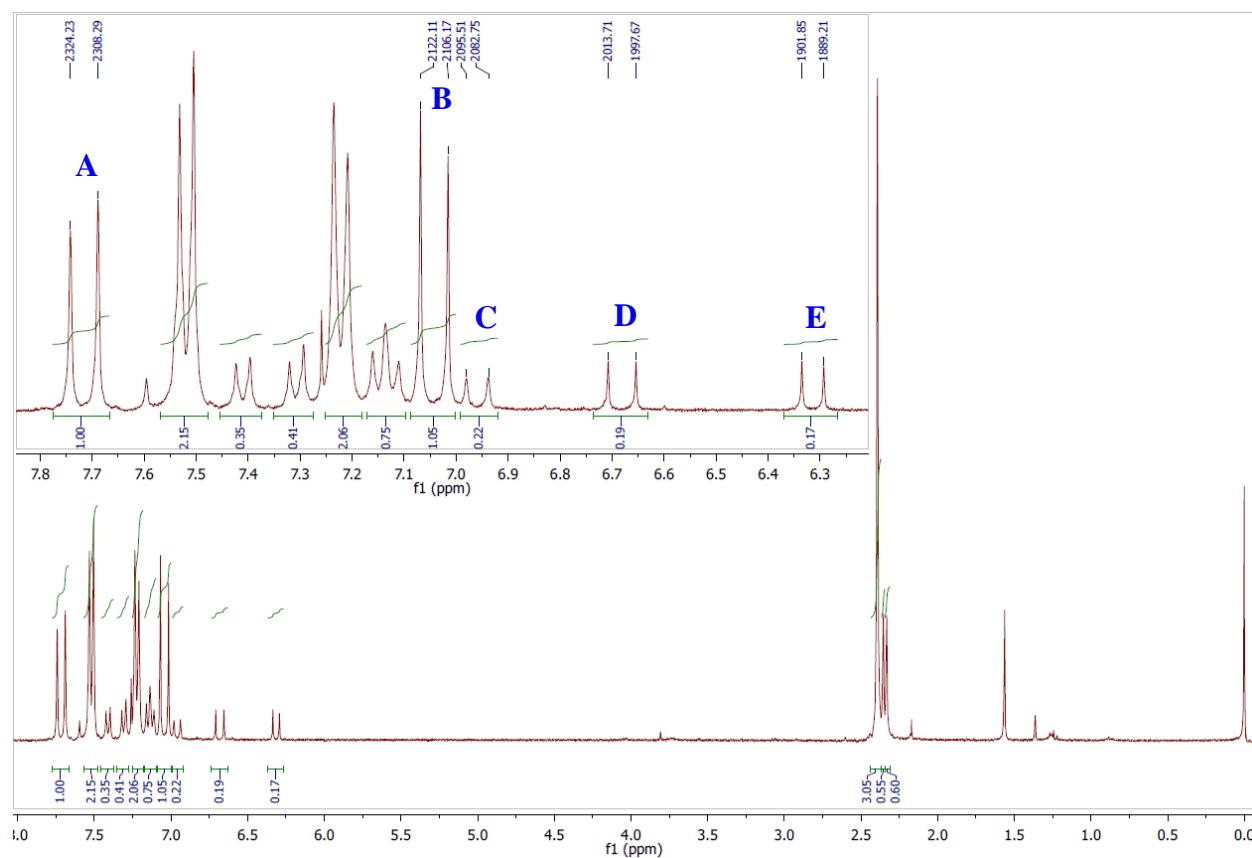

IX. An aldol condensation used in the organic laboratory at Madison College produced the stereoisomeric product mixture shown below.

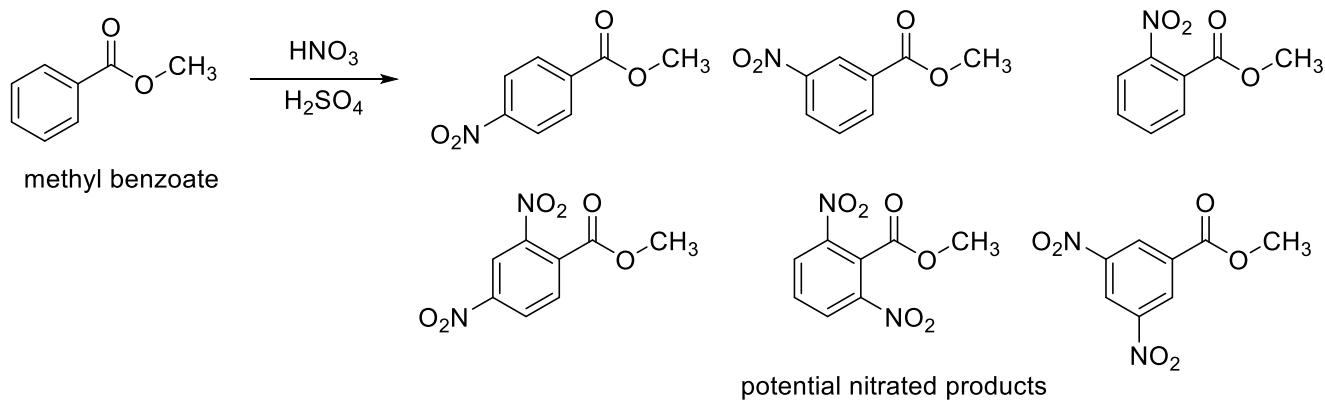

- A. For each of the stereoisomers, estimate the expected coupling constant ($J_{\alpha\beta}$) for $H_\alpha - H_\beta$ for each of the molecules.

- B. Unfortunately, only five of the six possible vinyl ^1H -atom signals (labeled A – E) are observable in the aromatic and vinyl regions of the product mixture. These integrals, however, are sufficient to determine the product ratio of this reaction. Use the coupling constants and integrals of the identified signals to estimate the product ratio. Use the most isolated signal integrals for each molecule.

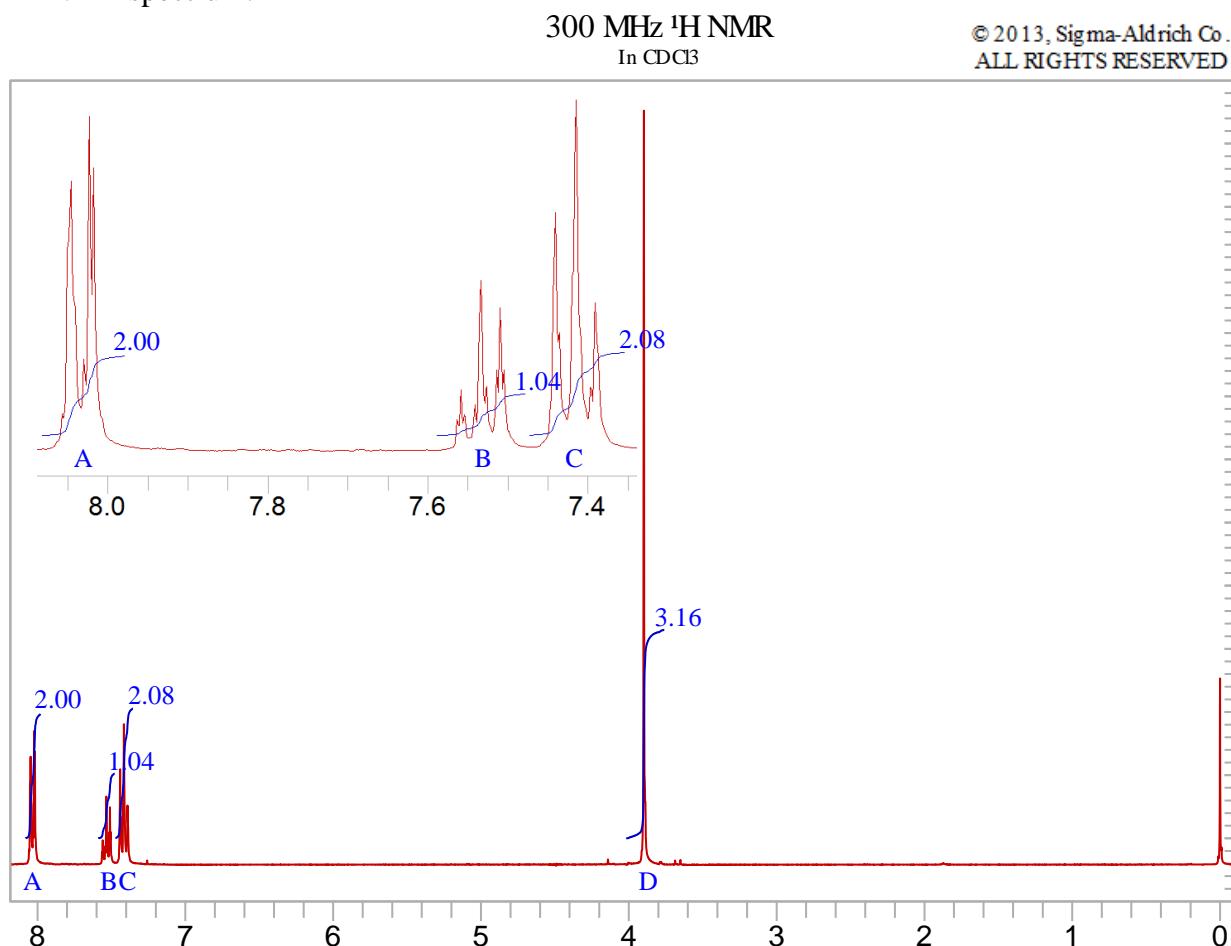

- X. An electrophilic aromatic substitution, the sulfuric acid-catalyzed nitration of methyl benzoate, was carried out in the Organic Chemistry Bootcamp at UW-Waukesha. The spectra presented below are from authentic student samples. Analyze the spectra to understand the outcome of this reaction.

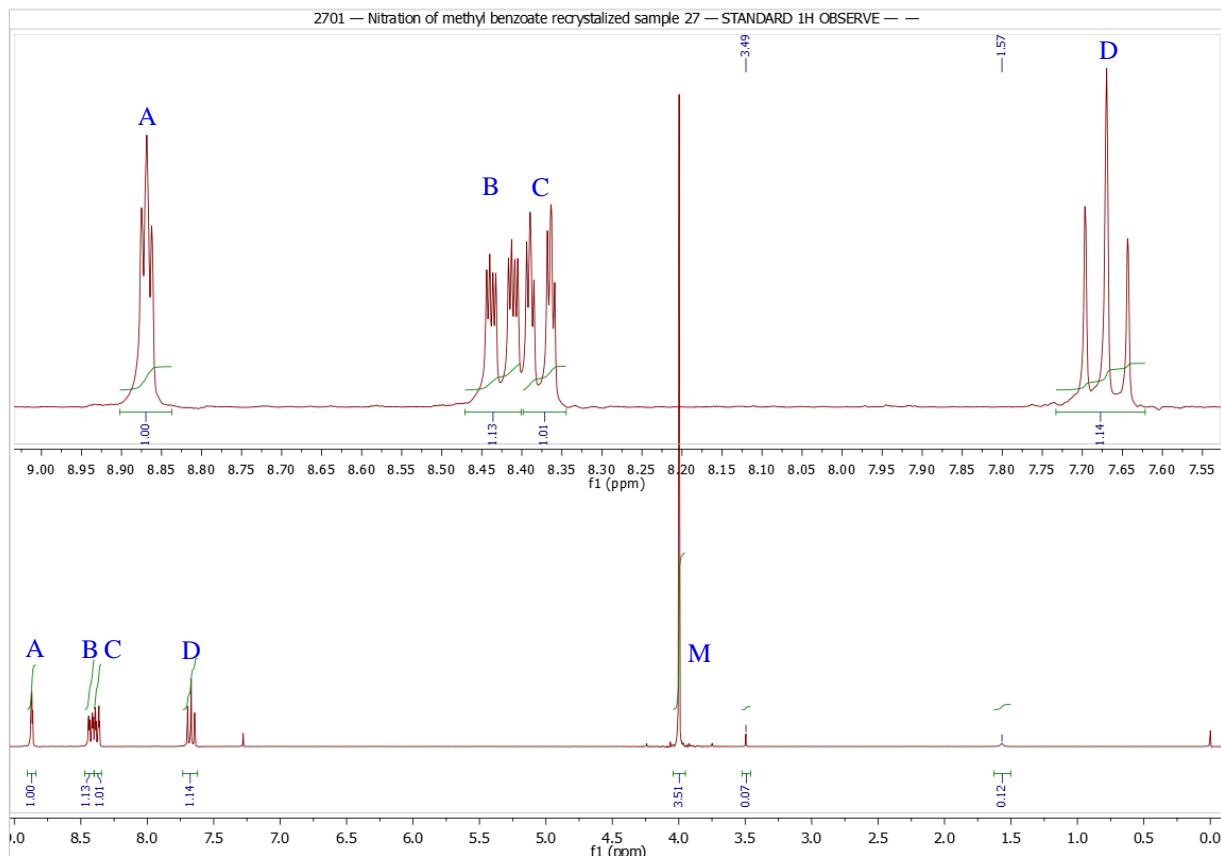

- A. Estimate the $^1\text{H-NMR}$ chemical shifts of the ^1H -atoms in methyl benzoate by analysis of the π conjugation using a series of resonance structures and by empirical (Curphy-Morison) parameters.
- B. Predict the expected fragmentation pattern of the molecular ion of methyl benzoate in an EI-Mass Spectrometer and provide a complete electron-pushing mechanism.

C. The authentic ^1H -NMR spectrum of methyl benzoate is provided below from the Aldrich database. Assign each of the signals to its corresponding ^1H -atom in methyl benzoate. Comment on how well the resonance structures and empirical parameters predicted the ^1H -NMR spectrum.

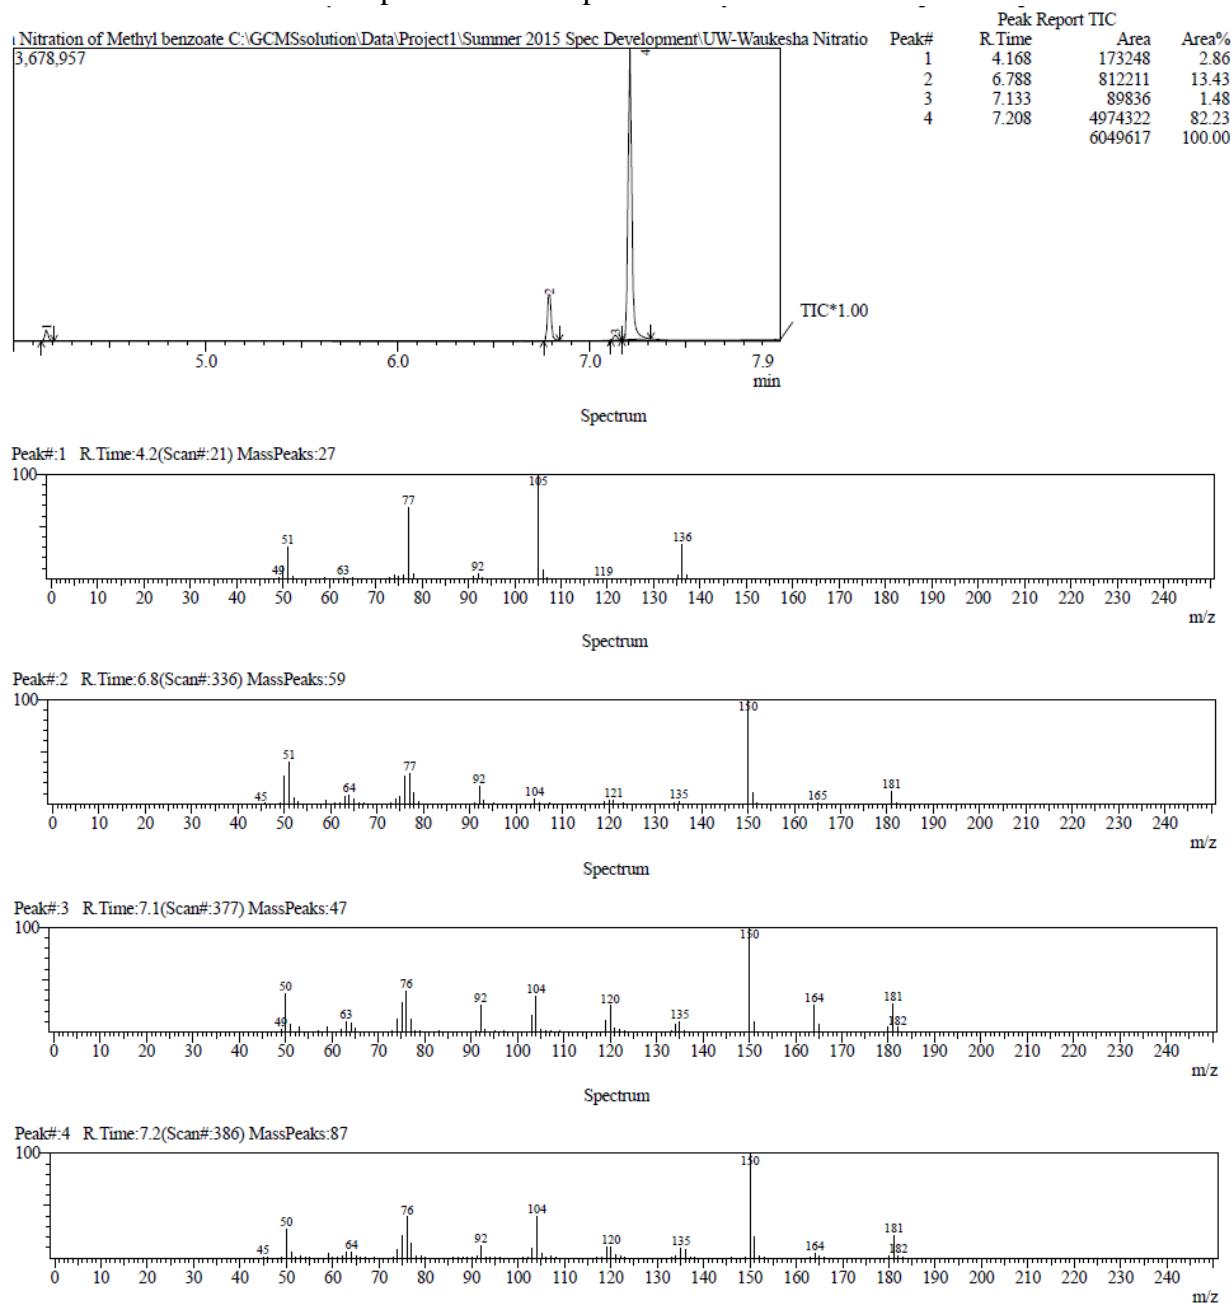

D. The major product of the EAS nitration of methyl benzoate was obtained after recrystallization in methanol; its $^1\text{H-NMR}$ spectrum is shown below.

- Assign the methanol, CHCl_3 and TMS signals.
- Determine the major product of the reaction and assign each of the $^1\text{H-NMR}$ signals to its corresponding ^1H -atom(s) in the major product.
- Justify the assignments with use of empirical (Curphy-Morrison) parameters.

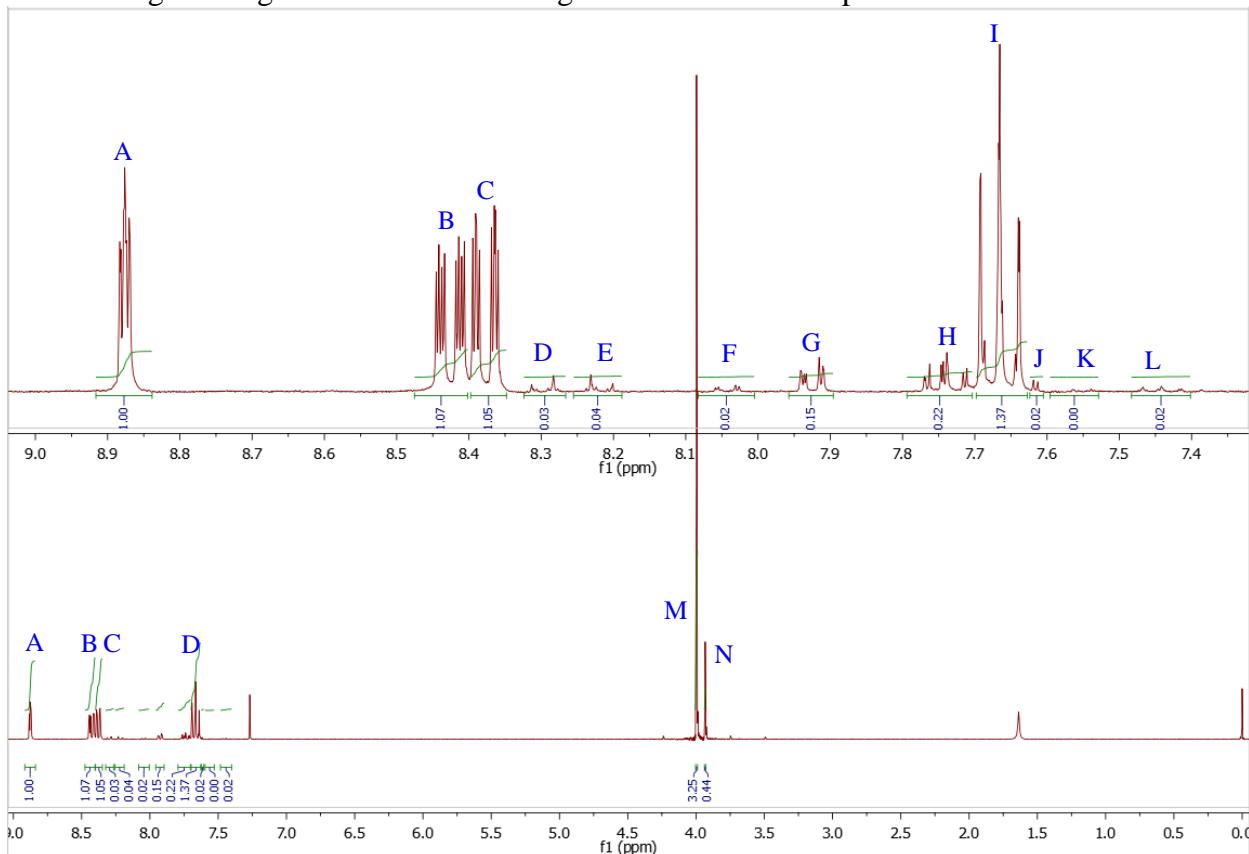

E. Prior to recrystallization, the crude product mixture was analyzed by GC-MS and the data are presented below. Determine the identity of the components of the mixture responsible for GC trace peaks 1 and 4. Provide a fragmentation mechanism to rationalize the major signals observed in the EI-Mass spectrum of component 4.

F. Based upon their EI-Mass spectra, propose the identity of the components of the mixture responsible for the GC trace peaks 2 and 3. Use Curphy-Morrison parameters to predict the ^1H -NMR chemical shift of each of the ^1H -atoms in the proposed components 2 and 3. From the GC-MS alone, it is not possible for you to distinguish between these two components.

G. Use the GC-trace to determine the ratio of components in the product mixture in order of relative abundance in the form of X:Y:Z:1.

H. The ^1H -NMR spectrum of the crude mixture is shown below. Assign the ^1H -atoms for all of the integrated signals in the aromatic region of the ^1H -NMR spectrum.

- I. Based upon the experimental data, comment on the regioselectivity of the nitration of methyl benzoate. Which product(s) are favored and which are disfavored?

- J. The Curphy-Morrison predictions of the $^1\text{H-NMR}$ chemical shifts of which component matches the most poorly to its experimental spectrum? Explain why the parameters do not predict the $^1\text{H-NMR}$ chemical shifts of the ^1H -atoms in this molecule to the same degree of accuracy as in the other molecules.
